

Version Control System (VCS) Explaining

The Version Control System is a tool that helps developers to see and know the actions made in the code, for example, changes, comments or things added to the code, this is very useful for developers that work in teams.

I think one of the benefits and ways to use VCS is that you can know and see a resume of the changes that were made in the code, also work with the code whenever you need and whichever place you at, you can know and see every single action and who made this action through Git, that helps a lot to continue working without the need of having all team with you.

An specific command that I think is very helpful is the commit (`git commit -m "#"`) with this command the developers can see the comments of any type of action that was made in the code.
